DSP algorithms shape DSPs
Design goals for embedded DSP
Comparing performance
When to use which
Conclusions

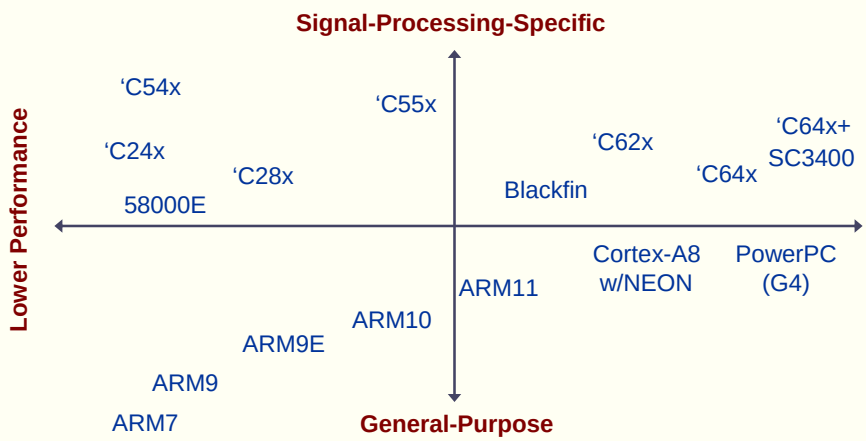
Definitions

Microprocessors–General-Purpose Processors (GPPs)
- 32-bit GPPs for embedded applications
  - E.g., ARM ARM7

Digital Signal Processors (DSPs)
- Microprocessors specialized for signal processing applications
  - E.g., Texas Instruments C55x+

DSP-enhanced GPPs and hybrids
- GPPs with added DSP features, or processors designed with DSP and GPP attributes
  - E.g., MIPS MIPS24KE, Microchip dsPIC, Analog Devices Blackfin

Example Processors



DSP Algorithms Shape DSPs

How Signal Processing is Different From Other Tasks

- Very computationally demanding
- Requires attention to numeric fidelity
- High memory bandwidth requirements
- Streaming data—and lots of it
- Predictable data access patterns
- Execution-time locality
- Math-centric
- Real-time constraints
- Standards: algorithms, interfaces

DSP Algorithms Shape DSPs

Computational demands	→	Multiple parallel execution units, hardware acceleration of common DSP functions
Numeric fidelity	→	Accumulator registers, guard bits, saturation hardware
High memory bandwidth	→	Harvard architecture, support for parallel moves
Predictable data access patterns	→	Specialized addressing modes, e.g., modulo, bit-reversed

DSP Algorithms Shape DSPs

Execution-time locality	→	Hardware looping, streamlined interrupt handling
Math-centricity	→	Single-cycle multiplier(s) or MAC unit(s), MAC instruction
Streaming data	→	Data memory usually SRAM, not cache; DMA
Real-time constraints	→	Few dynamic features, on-chip SRAM instead of cache
Standards	→	16-bit data types; rounding, saturation modes

Example: Video Processing

- Computational demands: high
  - Example: color conversion
    - CIF (352 by 288 pixel) , 15 fps, conversion (without any interpolation) requires over 18 million operations per second
- Numeric fidelity: 8 to 12-bit pixels
- High memory bandwidth
  - E.g., D1 video (720x480), 30 fps
    - (720*480 pixels) (3 RGB values) (8 bits) (30 frames) = 31.1 Mbytes/second
- Highly parallelizable
- Predictable data access patterns
  - Motion estimation and compensation notable exceptions

Processor Loading for Video Decoder

Performance

- Data path
  - Computational resources
  - SIMD
- Memory architecture
  - Harvard vs. Von Neumann
  - Cache vs. SRAM with DMA
- Real-time considerations
  - Non-determinism
  - Dynamic features

Comparing DSPs and GPPs
Data Path

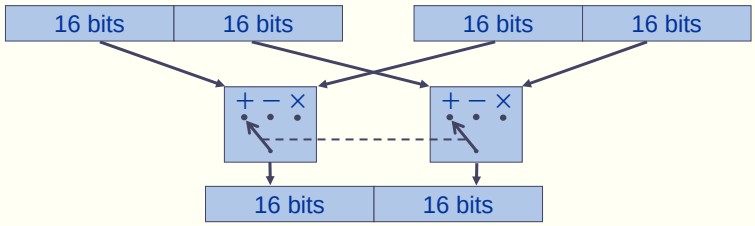
Low-end DSP	Low-end GPP
Dedicated hardware performs all key arithmetic operations in 1 cycle	Multiplies often take >1 cycle
	Multi-bit shifts often take >1 cycle
Usually 16-bit, fractional, integer	Usually 32-bit, integer only
Hardware support for managing numeric fidelity • Guard bits, saturation, rounding modes, …	Saturation, rounding typically take extra cycles
Limited bit-manipulation capabilities	May have superior bit-manipulation capabilities

Comparing DSPs and GPPs
Data Path

High-performance DSP	High-performance GPP
Up to 8 arithmetic units	1-3 arithmetic units
Some specialized arithmetic units • E.g., MAC unit, Viterbi unit	General-purpose arithmetic units • E.g., integer unit, floating-point unit
Support multiple data sizes	Support multiple data sizes
Limited to excellent bit-manipulation capabilities	May have superior bit-manipulation capabilities
Hardware support for managing fixed-point numeric fidelity	Saturation, rounding typically take extra cycles

SIMD

Single Instruction, Multiple Data



Performs the same operation simultaneously on multiple sets of operands

- Under the control of a single instruction

Some SIMD processors support multiple data widths (for example, 32-bit, 16-bit, and 8-bit)

Comparing DSPs and GPPs

SIMD Features

Low-end DSP & GPP

DSPs: very limited SIMD features

- E.g., dual add, subtract of 16-bit fixed-point data

GPPs: No SIMD support

High-performance DSP & GPP

DSPs: limited to extensive SIMD features

- E.g., TigerSHARC
  - 4 x 32-bit float
  - 4 x 32-bit integer
  - 8 x 16-bit integer
  - 16 x 8-bit integer

GPPs: extensive SIMD features

- E.g., PowerPC 74xx
  - 4 x 32-bit float
  - 4 x 32-bit integer
  - 8 x 16-bit integer
  - 16 x 8-bit integer

Comparing DSPs and GPPs
SIMD Features

DSP-enhanced GPP

Moderate to extensive SIMD features
- E.g., ARM1136J-S
  - 1 × 32-bit integer
  - 2 × 16-bit integer
  - 4 × 8-bit integer

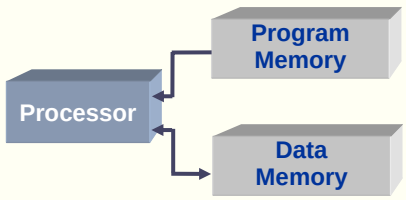
Memory Structure

- Harvard vs. Von Neumann
  - Harvard – separate memories for data and instructions
  - Von Neumann – single memory for data and instructions
- Bandwidth between processor and on-chip memory
- Size of on-chip memory
  - Larger memory is better for performance, but hurts cost and increases power
  - Fetching data from external memory consumes cycles and power
- Memory control
  - Caches
  - SRAM with DMA

Comparing DSPs and GPPs
Memory Architecture

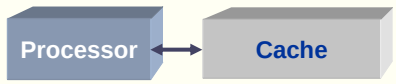
Low-end DSP

Harvard architecture
2-4 memory accesses per cycle
No caches; on-chip SRAM
DMA



Low-end GPP

Von Neumann architecture
Typically 1 access per cycle
Typically use cache(s)

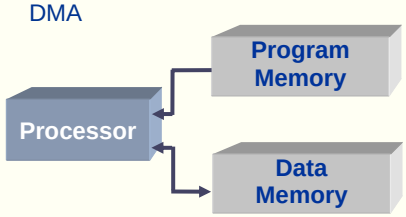


Comparing DSPs and GPPs
Memory Architecture

High-performance DSP

Harvard architecture
Per cycle accesses:
- 1-8 instructions
- Two or more 16- to 64-bit data words

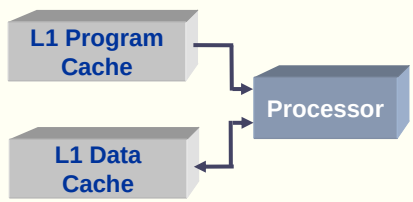
Sometimes caches, often lockable, configurable as SRAM
DMA



High-performance GPP

Harvard architecture
Per cycle accesses:
- 1-4 instructions
- ~Two 32- to 64-bit or one 128-bit data word

Use caches



Real-Time Considerations

- Performance
  - Can the processor handle the load?
- Non-determinism
  - Non-determinism causes load variance
  - Complicates optimization and debugging
  - Caused by:
    - Dynamic processor features
    - Data-dependent algorithm behavior
    - Multi-tasking

Comparing DSPs and GPPs
Dynamic Features

Dynamic features are common in high-end GPPs to boost performance

- Superscalar execution
- Caches
- Branch prediction
- Data-dependent instruction execution times

These features are occasionally used in DSPs, too

Comparing DSPs and GPPs

Dynamic Features

Low-end GPPs and DSPs	High-performance GPPs and DSPs
GPPs: • Dynamic caches common	GPPs: Moderate to extensive use of dynamic features • Dynamic caches standard • Superscalar execution, branch prediction common
DSPs: • Rarely have dynamic features	DSPs: Mostly avoid dynamic features • Cache is most common dynamic feature • Superscalar execution rare • Branch prediction sometimes used

Comparing DSPs and GPPs

Caches: Challenges

Caches work by lowering *average* access time
- They are effective at doing this in many applications
- But access times vary significantly

Some applications are sensitive to *maximum* access time
- E.g., many “hard-real-time” signal processing applications

Signal processing access patterns are often predictable
- Thus, DMA may be preferable to a cache
- Some caches provide pre-fetching capability
- Some DSPs’ caches can be locked or configured as part cache, part SRAM

Comparing DSPs and GPPs

Branch Prediction: Strengths and Weaknesses

In many applications, branch prediction is very accurate

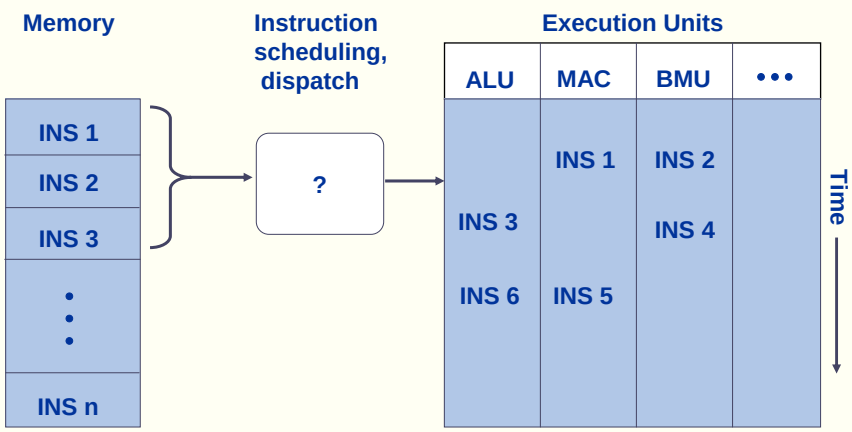
- This includes signal processing applications, where most branches are part of for-next loops

Complex branch prediction algorithms introduce timing uncertainty

- It can be difficult to predict whether the prediction will be correct at any given instant

Multi-Issue Approaches

VLIW vs. Superscalar



Comparing DSPs and GPPs

Trade-offs: Superscalar vs. VLIW

Superscalar (high-performance GPPs, mostly)

- Increased hardware complexity
  - Silicon area, power consumption
- Dynamic behavior
  - Complex performance model, timing variability
- Increased performance with binary compatibility
- Decreased software complexity (programmer/compiler)

VLIW (high-performance DSPs, mostly)

- Decreased hardware complexity
- No dynamic behavior
- Binary compatibility difficult (downward direction)
- Increased software complexity

Processor Selection Factors for Embedded Signal Processing Applications

Performance
Development Effort
Development Risk
Roadmap Risk
Cost
Size
Power

Development Effort

Compiler friendliness

- GPPs generally have the advantage
- SIMD difficult for compilers, whether GPP or DSP
  - Often requires assembly programming or use of intrinsics—both of which complicate software development

Development support

- DSPs have more 3rd party DSP-oriented IP, DSP-oriented tools
- GPPs have better non-DSP-oriented support

Comparing DSPs and GPPs

Instruction Set

Low-end DSP	Low-end GPP
Specialized, complex instructions	General-purpose instructions
Multiple operations per instruction	Typically only one operation per instruction
Poor orthogonality	Good orthogonality

```
mac x0,y0,a x:(r0)+,x0 y:(r4)+,y0
```

```
mpy  r2,r3,r4
add  r4,r5,r5
mov  (r0),r2
mov  (r1),r3
inc  r0
inc  r1
```

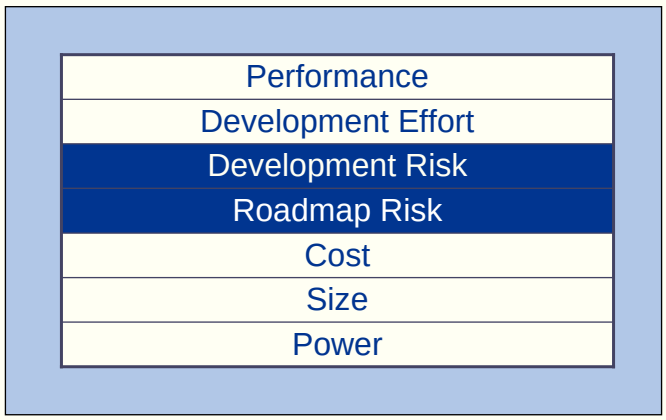
Comparing DSPs and GPPs
Instruction Set

High-performance DSP	High-performance GPP
	Baseline:
Simple to moderately-complex instructions	Simple instructions
Moderate to excellent orthogonality	Moderate to excellent orthogonality
	With SIMD extensions:
	Moderately complex instructions
	Moderate to excellent orthogonality

Comparing DSPs and GPPs
Development Support

	DSPs	GPPs
Tools in general	Primitive to moderately sophisticated	Primitive to very sophisticated
DSP-specific tool support	Good to excellent E.g., cycle-accurate simulators, DSP C extensions	Poor but improving E.g., general lack of cycle-accurate simulators
3rd-party DSP software support	Poor to excellent	Limited but growing
Non-DSP 3rd-party software support	Limited but growing Few to moderate RTOS options	Extensive Few to extensive RTOS options
Links w/other high-level tools	E.g., MATLAB	E.g., GUI builders

Processor Selection Factors for Embedded Signal Processing Applications



Comparing DSPs and GPPs

Compatibility and Availability

Low-end DSP	Low-end GPP
Mostly proprietary architectures • I.e., one architecture, one vendor	Many shared architectures • I.e., one architecture, several (to many) vendors
Varying compatibility between successive generations	Often binary compatibility between successive generations
Rarely available as licensable core	Often available as licensable core • E.g., ARM, MIPS

Comparing DSPs and GPPs
Compatibility and Availability

High-performance DSP	High-performance GPP
Mostly proprietary architectures	Mostly shared architectures • PowerPC, MIPS, ARM, x86
Sometimes binary compatibility between successive generations • E.g., 'C6xxx	Usually binary compatibility between successive generations
Rarely available as licensable core • E.g. CEVA-X	Sometimes available as licensable core • E.g., ARM, MIPS

Processor Selection Factors for Embedded Signal Processing Applications

Cost

- Hardware cost
  - System cost
    - Chip cost
    - On-chip integration
      - Fewer components may lower component costs
  - SoC cost
    - Die size
      - Dynamic features use silicon (e.g., superscalar vs. VLIW)
    - Royalties

Comparing DSPs and GPPs

On-Chip Integration

Low-end GPPs and DSPs	High-performance GPPs and DSPs
Typically, wide range of on-chip peripherals and I/O interfaces	Moderate to extensive on-chip integration • PC CPUs offer very little on-chip integration
Often oriented towards consumer applications • E.g., USB, serial ports, I²S, GPIO, …	Often oriented towards specific applications • Viterbi decoding coprocessors, UTOPIA ports, …

Power

Processor Selection Factors for Embedded Signal Processing Applications

Performance
Development Effort
Development Risk
Roadmap Risk
Cost
Size
Power

Power

- Parallelism
  - Parallel computation allows lower clock rate…
  - But may increase leakage current
- Suitability of instruction set
  - A better matched instruction set allows lower clock rate
- Dynamic features
  - Caches may cause data/instruction traffic increase
  - Superscalar – hardware scheduling consumes power
- On-chip integration
  - Memory architecture
    - Fetching data from external source expensive
  - Smart peripherals aid parallelism, may enable more processor sleep time
- Power-management features

Comparing Performance

When evaluating processors for signal processing, application-specific, product-specific considerations dominate

- Relative performance can vary dramatically depending on the benchmark

Vendor performance claims should be viewed skeptically

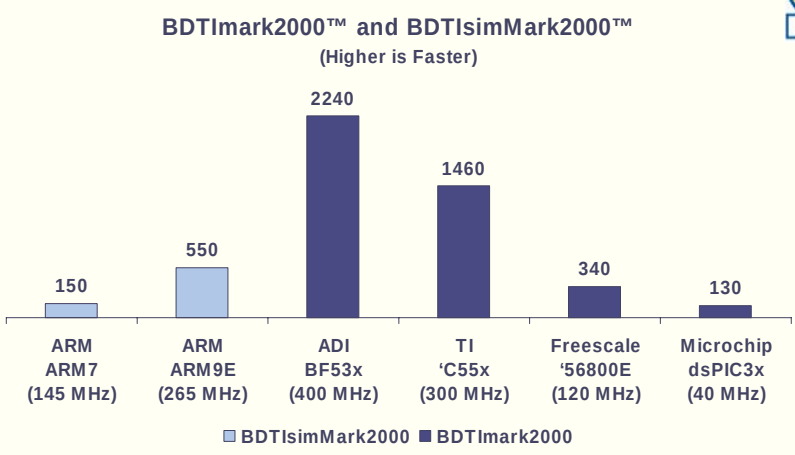
- "MIPS" = …
- Benchmarks are a sharp tool

Performance is more than speed

- Cost/perf, energy efficiency, memory use…

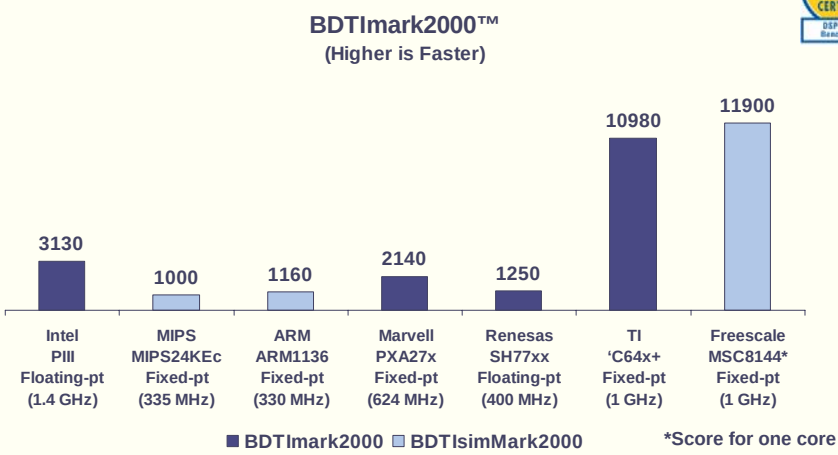
Comparing Performance

Speed: Low-end DSPs/GPPs (Below $10)



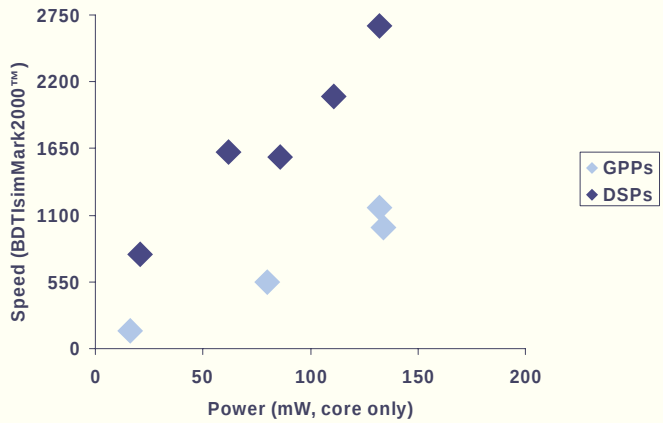
Comparing Performance

Speed: High-performance DSPs/GPPs



Comparing Performance

Speed vs. Power: Licensable Cores



All data assumes use of TSMC CL013G process and ARM Artisan SAGE-X library

When Should You Consider a DSP?

- You need maximum performance or efficiency on a signal-processing-heavy workload
- You have compatible software you want to re-use
- Your developers are already familiar with it
- You need limited non-signal-processing software
- You'll be developing demanding DSP software
- A DSP offers good off-the-shelf software for your application
- You don't need a full-featured operating system
- You need maximum execution-time determinism
- A DSP offers superior integration

When Should You Consider a GPP?

- A GPP offers sufficient performance and efficiency on your signal-processing-heavy workload
- You have compatible software you want to re-use
- You want to be able to switch vendors but not ISAs
- Your developers are already familiar with it
- You need extensive non-signal-processing software
- You won't be developing much DSP software
- A GPP offers good off-the-shelf software for your application
- You need a full-featured operating system
- Execution-time determinism is not critical
- A GPP offers superior integration

Can I Have the Best of Both Worlds?

Maybe.

Options include:

- Two processors
  - One or two chips
  - But: Cost; multiprocessor software development
- DSP-enhanced GPP
  - But: Typically compromise on DSP-oriented tools, software, integration
- Hybrid
  - But: Typically compromise on GPP-oriented tools, software
- Media processors / application processors
  - But: Tend to be focused on multimedia applications
